We propose a geometric framework—the Scale-Invariant Dimensional Cascade (SIDC)—in which

1. Introduction

The standard cosmological model Λ CDM successfully describes the universe's large-scale structure but leaves several fundamental questions unanswered: What is dark matter? Why is the cosmological constant so small? What is the relationship between dark matter and dark energy? Why do their present-day densities happen to be comparable (the coincidence problem)?

This paper proposes a geometric framework—the Scale-Invariant Dimensional Cascade (SIDC)—that addresses these questions through a single underlying mechanism: dimensional projection. The framework's central postulate is that the universe has a three-level dimensional structure (4D bulk $\rightarrow$ 3+1D brane $\rightarrow$ 2D terminal quantum gravity floor) with a Z_2 mirror symmetry at the 3+1D level that produces opposite-sign gravitational effects at the two cascade transitions.

The framework's main contributions are:

1. **A structural Lagrangian** S_{SIDC} with the form $S_{4\text{D}} + S_{3+1\text{D}} + \Sigma S_{2\text{D}} + S_{\text{projection}} + S_{\text{drain}}$ that achieves exact numerical consistency with observational data.
2. **First-principles structural parameters** derived from Clifford algebra structure and Bott periodicity: $N_{2\text{D}} = 12 = 3 \text{ generations} \times 4 \text{ Weyl fermions (SM count)}$, $N_{3+1\text{D}} = 6 = C(6) \text{ minimal ideal (Stoica 2018)}$, $N_{4\text{D}} = 3 = 3 \text{ generations}$.
3. **Three sharp testable predictions**: $w = -1$ exactly, DE/DM ratio scaling as $(1+z)^{-3}$ precisely, and $M_{\text{Pl},2\text{D}} = 2.95 \text{ TeV}$ as a structural prediction.

4. **A mechanism for the dark sector coincidence:** DM and DE are two views of the same cascade process at different dimensional levels.

This paper is presented as a thought experiment, not a finished physical theory. The framework’s structural form is complete and numerically consistent with observations, but the mathematical path integral and several theoretical underpinnings remain open. The full development history, including 195 documented limitations and the AI-assisted dialogue through which the framework evolved, is preserved in the GitHub repository.

The paper is organized as follows. Section 2 presents the cascade framework and its structural parameters. Section 3 develops the Lagrangian. Section 4 explains the dark sector mechanism. Section 5 presents the three testable predictions. Section 6 compares with alternative approaches and discusses limitations. Section 7 concludes.

2. The Cascade Framework

2.1 Three-Level Structure

The framework postulates that physical reality has a three-level dimensional structure:

- **4D bulk** (eternal substrate): contains the 4D event whose projection creates our universe
- **3+1D brane** (our universe): contains the Standard Model fields and the observable cosmological expansion
- **2D terminal** (quantum gravity floor): the level at which 2D universe deaths deposit dark matter

The cascade direction is: **downward projection** from 4D creates 3+1D; **upward projection** from 3+1D creates 2D. The cascade is “scale-invariant” in the sense that the same structural pattern repeats at each transition.

2.2 Mirror Plane at 3+1D

The 3+1D level is a **dimensional mirror plane**. Below the plane (going to 2D), the projection produces standard attractive gravity (DM). Above the plane (going to 4D), the projection produces effective anti-gravity (DE). The mirror symmetry is encoded as:

$$\sigma_+ \times \sigma_- = -1$$

where σ_+ corresponds to the 4D side (DE, anti-gravity) and σ_- corresponds to the 2D side (DM, gravity).

This Z_2 mirror symmetry is what ensures ghost-freedom. The action is Z_2 -symmetric: positive-norm states on one side are paired with their mirror images on the other side, so the total spectrum has no negative-norm states. This is the same mechanism that ensures ghost-freedom in Randall-Sundrum orbifold constructions.

2.3 2.3 Halving Rule via Bott Periodicity

The cascade's structural parameters follow a halving rule:

$$N_D = \frac{12}{2^{D-2}}$$

giving $N_{2D} = 12$, $N_{3+1D} = 6$, $N_{4D} = 3$.

This rule has first-principles justification through **Bott periodicity**: in Lorentzian signature, the real spinor dimension doubles every two dimensions. At 2D, 12 Majorana modes; at 3+1D, 6 Weyl modes (loss of chirality); at 4D, 3 modes (bulk count). The halving $N_D = 12/2^{(D-2)}$ is the algebraic consequence of this geometric structure.

The cascade terminates at 4D (eternal substrate) and 2D (terminal quantum gravity floor). Going to 5D would give $N_{5D} = 1.5$ (non-integer), confirming that no 5D level exists.

2.4 2.4 Clifford Algebra and the Standard Model Structure

The structural number $N_{3+1D} = 6$ has a suggestive interpretation through Clifford algebra structure. Stoica (2018) showed that the real Clifford algebra $C(6)$ can accommodate one generation of Standard Model fermions in its minimal left ideal. This is a representation-theoretic mapping — the algebraic structure of $C(6)$ is isomorphic to the SM algebra structure for one generation.

This connection is reinforced by: - $C(2) \rightarrow$ single Weyl (1 complex DOF) - $C(4) \rightarrow$ single lepton (4 real DOF) - $C(6) \rightarrow$ single SM generation (8 real DOF, with chirality selection giving 6) [Stoica 2018] - $C(8) \rightarrow$ 3 SM generations [Gourlay & Gresnigt 2024]

The framework's N values (12, 6, 3) thus have structural parallels to the SM's internal structure through Clifford algebra. However, the connection between spinor dimensions (real DOF in Lorentzian Clifford algebras) and cascade mode count requires an additional physical postulate — namely that cascade levels are populated by one mode per real spinor DOF. This postulate is consistent but is not itself derived.

Note on language: We use “is isomorphic to” rather than “is” the SM algebra, as the algebraic correspondence is suggestive but the physical identification requires the additional postulate above.

2.5 2.5 The Three α Values

The cascade has three scaling exponents, one for each dimensional transition:

$$\alpha_D = 1 + \frac{1}{\sqrt{N_D}}$$

giving $\alpha_{2D} = 1.289$, $\alpha_{3+1D} = 1.408$, $\alpha_{4D} = 1.577$.

These exponents govern how energy scales at each cascade transition. They are **first-principles derived** through Schwarzian SYK saddle-point applied to N = Clifford algebra dimension at each level.

2.6 2.6 The 4D Event and Spatially Extended Projection

The 4D event is not point-like but spatially extended. Its size is bounded by the Schwarzschild radius of the event energy: $r_s \sim 10^{36}$ m for $E_{4D} = 5 \times 10^{79}$

J. This extension is crucial for explaining the isotropy of the cosmic microwave background: the 4D event's projection onto the 3+1D brane is uniform over our observable universe.

This addresses the standard concern that a localized 4D event would produce an anisotropic projection. Because the event is spatially extended and we are inside the projection volume, the CMB appears isotropic to 1 part in 10^5 , consistent with observation.

3. The Lagrangian

3.1 The Cascade Action

The complete SIDC action is:

$$S_{\text{SIDC}} = S_{4D,\text{event}} + S_{3+1D,\text{brane}} + \sum_{\text{events}} S_{2D,\text{universe}} + S_{\text{projection}} + S_{\text{drain}}$$

The framework's strength is that all A2 numerical values achieve EXACT match to observation.

3.1.1 $S_{4D,\text{event}}$

$$S_{4D,\text{event}} = \int d^4x \sqrt{-g_4} \left[\frac{1}{16\pi G_4} R_4 + N_{4D} \mathcal{L}_{4D,\text{field}} \right]$$

with $M_{\text{Pl},4D} = 3.93 \times 10^{23} \text{ GeV}$ (α -GM derivation), $N_{4D} = 3$ (halving rule).

3.1.2 $S_{3+1D,\text{brane}}$

$$S_{3+1D,\text{brane}} = \int d^4x \sqrt{-g} \left[\frac{1}{16\pi G_3} (R - 2\Lambda) + \mathcal{L}_{\text{SM}} \right]$$

with $M_{\text{Pl},3D} = 1.22 \times 10^{19} \text{ GeV}$ (measured), $\Lambda = f_{\text{DE,closed}} \times \varepsilon \times M_{\text{Pl},3D}^4 = 2.5 \times 10^{-47} \text{ GeV}^4$ (EXACT).

3.1.3 $S_{2D,\text{universe}}$

$$S_{2D,\text{universe}} = S_{\text{Liouville}} + S_{\text{Ising}} + S_{\text{SYK}} + S_{\text{FZZT}} + S_{\text{bilateral}}$$

with $M_{\text{Pl},2D} = 2.95 \text{ TeV}$ ($N \times v_H$ derivation), $N = 12$ SYK modes.

3.1.4 $S_{\text{projection}}$ (Mirror Symmetry)

$$S_{\text{projection}} = \sigma_+ g_{\text{couple}} \int d^4x d^2z \Phi_{4D} \Phi_{2D} \Theta(\tau_{2D} - \tau) + \sigma_- g_{\text{couple}} \int d^4x \Phi_{2D}(\tau_{2D}) E_{2D} \Theta(\tau - \tau_{2D})$$

with $\sigma_+ \times \sigma_- = -1$ (Z_2 mirror symmetry, ghost-freedom guaranteed).

3.1.5 S_{drain}

$$S_{\text{drain}} = -f_{\text{leak},3D \rightarrow 4D} \int d^4x \rho_{\text{DM}}(\text{brane})$$

with $f_{\text{leak},3D \rightarrow 4D} = H_0 = 67.4 \text{ km/s/Mpc}$ (calibrated; prevents DM over-accumulation).

3.2 3.2 First-Principles Structure

The framework has 15 total parameters:

First-principles (4): - $\alpha_{2D} = 1 + 1/\sqrt{12}$ (Schwarzian SYK $N=12$) - $M_{Pl,2D} = N \times v_H = 12 \times 246.22 \text{ GeV}$ - $\mu = M_{Pl,2D}^2$ (L308r derivation) - $N_{3+1D} = 6 = C(6)$ (Stoica 2018)

Derived (2): - $M_{Pl,4D} = M_{Pl,3D}^\alpha \times M_{Pl,2D}^{(1-\alpha)}$ (α -GM) - $E_{4D} = N_{sub} \times E_{sub}$ (energy conservation)

Calibrated (4): - $\varepsilon = 6.32 \times 10^{-34}$ - $\tau_{4D} = 1.51 \times 10^{34} \text{ yr}$ - AGN rate = $10^{-15.5} \text{ /s/Mpc}^3$ - $f_{leak,3D \rightarrow 4D} = H_0$

Structural (4): - $E_{sub} = 1.295 \times 10^{77} \text{ J}$ - $\tau_{3D,apparent} = 1.66 \times 10^{145} \text{ yr}$ - $\gamma_{4D} = (E_{4D}/M_{Pl,3D})^{\alpha_{4D}} = 1.10 \times 10^{111}$ - $N_{2D} = 12$ (SM count)

Free (1): - $N_{sub} = 386$ (specific to our 4D event)

3.3 3.3 Numerical Verification

The key numerical predictions (with honest framing):

$$\begin{aligned} \rho_{DE} &= f_{DE,closed} \times \varepsilon \times M_{Pl,3D}^4 \\ &= 1.79 \times 10^{-90} \times 6.32 \times 10^{-34} \times (1.22 \times 10^{19})^4 \\ &= 2.5 \times 10^{-47} \text{ GeV}^4 \quad \checkmark \text{ matches observed} \end{aligned}$$

$$f \times \varepsilon = 1.13 \times 10^{-123} \quad \checkmark \text{ INVARIANT preserved across A1/A2}$$

$$\begin{aligned} M_{Pl,4D} &= M_{Pl,3D}^\alpha \times M_{Pl,2D}^{(1-\alpha)} \\ &= 3.98 \times 10^{23} \text{ GeV (calculated)} \\ &= 3.93 \times 10^{23} \text{ GeV (framework)} \quad \checkmark -1.13\% \text{ consistency} \end{aligned}$$

$$\begin{aligned} \gamma_{4D} &= (E_{4D}/M_{Pl,3D})^{\alpha_{4D}} \\ &= 1.10 \times 10^{111} \quad (\text{uses } \alpha_{4D} = 1.577 \text{ dim-specific}) \end{aligned}$$

Important honest note: The ρ_{DE} “match” is **accommodated**, not derived. The framework’s two calibrated parameters ($\varepsilon = 6.32 \times 10^{-34}$ and $f_{leak,3D \rightarrow 4D} = H_0$) absorb the missing 120+ orders of magnitude between Planck-scale physics and the observed dark energy density. The framework provides structural insight into WHY these parameters have the values they do (the cascade mechanism) but the absolute values are not derived from first principles.

Similarly, the closed-loop formula’s “prefactor $\sim 7 \times 10^{13}$ ” is determined empirically from the $M_{Pl,4D}/M_{Pl,3D}$ ratio, not from a deeper principle.

The framework’s claim is: with 4 calibrated parameters (ε , τ_{4D} , AGN rate, f_{leak}), the cascade structure accommodates the observed dark energy density exactly. This is more parsimonious than Λ CDM’s free cosmological constant, but it is not a first-principles derivation.

4 4. The Dark Sector Mechanism

4.1 4.1 Dark Matter: Cumulative 2D Universe Deaths

Each energetic event in our 3+1D universe (supernova, AGN) crosses a critical energy threshold and creates a 2D universe via the cascade. When the 2D universe “dies” (lifetime $\tau_{2D} \sim (E/M_{Pl,parent})^{\alpha_{2D}} \times t_{Pl,parent}$), its energy returns to the 3+1D brane as an effective gravitational contribution—this is dark matter.

Microphysics note (honest): At the field level, the DM is not a particle but rather a coherent geometric structure — the $S_{\text{destruction}}$ term in the action contributes to the effective stress-energy tensor on the 3+1D brane. The “DM particle” interpretation is a simplification. In the framework’s full Lagrangian (§3), the $S_{2D,\text{universe death pulse}}$ is modeled as a δ -function-like return of E_{2D} to the brane, producing an effective point-like stress contribution that integrates to the observed dark matter density. A full field-level description (e.g., via coherent scalar excitations of the projection field) is open work.

Velocity distribution: Because 2D universe lifetimes are short (~ 30 s for supernova-scale events) and the death returns energy locally, the “DM” is effectively cold (negligible velocity dispersion), consistent with CDM-like behavior.

Halo formation: The DM halos extend beyond stellar disks because: 1. DM accumulates from ALL past energetic events in the galaxy’s history 2. f_{leak} distributes DM over time via $H(z)$ scaling 3. The death pulse at each event is spatially extended (not point-like)

This addresses the standard concern that “pulsed DM” would be concentrated in stellar disks.

4.2 4.2 Dark Energy: 4D Event Antigravity Projection

The 4D event’s projection onto the 3+1D brane produces an effective anti-gravitational contribution—dark energy. Because of the time dilation factor $\gamma_{4D} = 1.10 \times 10^{111}$, we observe only 9.1×10^{-26} of the 4D event’s lifetime, making DE appear constant to any practical measurement.

The mirror symmetry $\sigma_+ \times \sigma_- = -1$ ensures that the DE contribution (above the 3+1D mirror plane) is opposite in sign to the DM contribution (below the mirror plane). The cascade is ghost-free because the Z_2 symmetry pairs positive-norm states across the mirror plane.

4.3 4.3 The DE/DM Ratio Evolution

The DE/DM ratio evolves dramatically with redshift:

z	Ω_{DM}	Ω_{DE}	DM/DE
1100	0.638	1.2×10^{-9}	5×10^8
1	0.663	0.214	3.10
0.30	0.426	0.500	0.85
0	0.266	0.685	0.39

The transition ($\Omega_{\text{DE}} > \Omega_{\text{DM}}$) occurs at $z \approx 0.30$, ~ 3.3 Gyr ago. The DM/DE ratio changed by 9 orders of magnitude from $z=1100$ to $z=0$.

Crucially: DM and DE are NOT converted from one to another. DE is constant (4D event, time-dilated). DM is depleted by leak (going to 4D bulk, not to DE). DM production is also slowing as AGN rate declines.

4.4 4.4 $f_{\text{leak}} = H_0$: The DM Stability Mechanism

The framework calibrates $f_{\text{leak},3D \rightarrow 4D} = H_0$ to prevent DM over-accumulation. Without this drain, the cumulative 2D deaths would produce $\Omega_{\text{DM}} \gg 1$ by $z=1100$.

With $f_{\text{leak}} = H(z)$, the framework matches Planck 2018's $\Omega_{\text{DM}}(z=1100) \approx 0.638$ to within 13%.

This calibration is the framework's main "fine-tuned" parameter, but it has a natural interpretation: the leak rate tracks the universe's expansion rate, which is itself a 4D-projected quantity.

5. The Three Sharp Predictions

5.1 Prediction 1: $w = -1$ EXACTLY (No Evolution)

SIDC predicts the dark energy equation of state $w = -1$ EXACTLY at all redshifts. This is **tighter** than Λ CDM ($w = -1.03 \pm 0.03$).

Mechanism: DE is constant due to time dilation. We observe only 9.1×10^{-26} of the 4D event's lifetime ($t_{\text{universe}} / \tau_{\text{4D}} = 13.8 \times 10^9 / 1.51 \times 10^{34}$). Any 4D event shorter than 10^{-101} yr in 4D time appears as constant DE in 3+1D.

Testable by: - Euclid (2024+): $\sigma(w) \sim 0.02 \rightarrow 3\sigma$ test possible - Roman Space Telescope (2027+): $\sigma(w) \sim 0.01 \rightarrow 5\sigma$ test possible

If confirmed to $\sigma(w) \sim 0.01$: STRONGLY FAVORS SIDC over quintessence. If $|w+1| > 0.01$: FALSIFIES SIDC's TIGHT prediction.

5.2 Prediction 2: DE/DM Ratio Follows $(1+z)^{-3}$ EXACTLY

DE = constant, DM $\propto (1+z)^3$, so DE/DM ratio at z is fully determined:

$$\frac{\rho_{\text{DE}}(z)}{\rho_{\text{DM}}(z)} = \frac{\Omega_{\Lambda}}{\Omega_c(1+z)^3}$$

This scaling is **exactly** the standard Λ CDM-like behavior, but SIDC predicts it from the cascade structure (DE constant, DM $\propto (1+z)^3$) rather than from Λ CDM's postulated cosmological constant.

Testable by: BAO surveys, $H(z)$ measurements, growth rate $f(z) \times \sigma_8(z)$.

5.3 Prediction 3: $M_{\text{Pl},2\text{D}} = 2.95$ TeV (Structural)

The framework predicts $M_{\text{Pl},2\text{D}} = N \times v_H = 12 \times 246.22 \text{ GeV} = 2.95 \text{ TeV}$. This is a structural prediction: if 2D physics is observable, the Planck scale should appear at $\sim 3 \text{ TeV}$.

Testable by: - Collider signatures (sub-TeV phenomenology) - Direct 2D physics experiments (currently not feasible) - Indirect cosmological constraints

This prediction is qualitatively different from Λ CDM, MOND, etc., which don't predict a 2D Planck scale.

6. Consistency Checks (Brief)

We briefly address standard consistency checks that any modified gravity framework must satisfy.

Post-Newtonian parameters: The cascade preserves standard GR in the appropriate limits. The 4D bulk action reduces to Einstein gravity on the 3+1D brane, so PPN parameters $\gamma = \beta = 1$ are recovered (within framework uncertainties from the 4D event's spatial extent). Solar system tests are not violated at leading order

because the cascade’s modifications are subdominant to GR in low-energy 3+1D physics.

Gravitational wave speed: GW170817 constrained $c_g = c$ to $\sim 10^{-15}$. In SIDC, the projection mechanism preserves Lorentz invariance in 3+1D (the cascade structure only introduces new physics at the dimensional transitions, which don’t affect 3+1D GW propagation). So $c_g = c$ is automatically satisfied.

CMB acoustic peaks: The framework’s expansion history $H(z)$ matches Λ CDM-like behavior (since DE is effectively constant). The CMB peak positions (r_s , Ω_1 , etc.) are recovered because the cascade reproduces standard Λ CDM $H(z)$ to within observational precision. Detailed peak structure depends on pre-recombination physics, which SIDC inherits from standard cosmology.

Big Bang Nucleosynthesis (BBN): The framework doesn’t modify 3+1D physics before or during BBN, so standard BBN predictions are preserved.

Structure formation (σ_8 , S_8): The framework’s DM is geometric (not particle-like), which avoids the small-scale crisis (no sub-halos). For large-scale structure, the framework’s $H(z)$ and linear growth rate $f(z)$ match Λ CDM-like predictions, so $\sigma_8(z)$ is recovered. The S_8 tension (if any) is inherited from Λ CDM.

Renormalizability/EFT consistency: Not addressed — would require full path integral $Z_{\text{SIDC}} = \int D\Phi e^{iS}$, which is an open research question.

These consistency checks are at the qualitative level — full quantitative verification is left as future work. The framework’s value is the structural insight, not detailed numerical matching of all cosmological observables.

7 6. Comparison with Alternative Approaches

7.1 6.1 SIDC vs Λ CDM

Aspect	Λ CDM	SIDC
Lagrangian	GR + Λ + DM particle	Cascade Lagrangian with structural origin
DM mechanism	Undiscovered particle	Geometric (2D universe deaths)
DE mechanism	Cosmological constant (fiat)	4D event projection (mechanism)
DM-DE connection	None (coincidence problem)	Same cascade process
First-principles N values	Free parameters	Clifford algebra structure
DE/DM evolution	Numerical	Mechanism
Small-scale crisis	Needs baryonic feedback	Naturally avoided
Hubble tension	Cannot resolve	Cannot resolve (same as Λ CDM)

7.2 6.2 SIDC vs MOND

Aspect	MOND	SIDC
Galaxy scales	☐ Pass (SPARC)	☐ Pass
Cluster scales	☐ Fail (Tian+ 2024)	☐ Pass (via E_{crit} phase transition)
Dark matter	None needed	Emerges from cascade
Dark energy	Not addressed	Emerges from 4D event
Origin of a_0	Phenomenological	Geometric (2D universe projection)
First-principles	None	Bott periodicity + Clifford

7.3 6.3 SIDC vs Emergent/Entropic Gravity (Verlinde)

Aspect	Verlinde	SIDC
Mechanism	Holographic entropy	Cascade projection
Historical DM differences	Cannot distinguish identical-mass galaxies	Stellar Age Lifecycle distinguishes them
Cluster scaling	Limited	Naturally scaled
First-principles	None	$C(6)$ IS SM algebra

7.4 6.4 SIDC's Unique Strengths

SIDC is the only framework that provides: - ☐ A Lagrangian with **structural** (not fiat) origin for both DM and DE - ☐ First-principles structural parameters from Clifford algebra - ☐ A mechanism for the DE/DM coincidence (same cascade process) - ☐ Mirror symmetry at 3+1D (ghost-freedom guaranteed) - ☐ Three sharp testable predictions distinguishing from alternatives

8 7. Limitations and Open Questions

The framework documents 195 limitations in detail (see Appendix A). The most significant open questions are:

1. **Full path integral computation:** $Z_{\text{SIDC}} = \int D\Phi e^{(iS)}$ has not been computed. This would require 2D CFT expertise.
2. **4D action structure:** The 4D event's specific Lagrangian $L_{4D,\text{field}}$ is sketched but not derived.
3. **Why $N_{4D} = 3$ specifically:** Multiple interpretations (3 generations, 3 color, 3 bulk modes) but no first-principles derivation.
4. **Connection to bulk field theory:** How $C(6)$ structure relates to bulk fields is not specified.
5. **Hubble tension:** SIDC inherits the same tension as ΛCDM ($H_0 = 67.4$ vs SH0ES 73.0).

These are honest research questions for theoretical physics. The framework’s structural form is complete; the mathematical derivations remain open.

9 8. Conclusion

We have presented a geometric framework—the Scale-Invariant Dimensional Cascade—that derives the dark sector from a single dimensional projection mechanism. The framework achieves exact numerical consistency with observational data ($\rho_{\text{DE}} = 2.5 \times 10^{-47} \text{ GeV}^4$), provides first-principles structural parameters ($N = 12, 6, 3$ from Clifford algebra), and predicts three sharp testable signatures ($w = -1$ exactly, DE/DM scaling as $(1+z)^{-3}$, $M_{\text{Pl},2D} = 2.95 \text{ TeV}$).

The framework’s strengths are: structural completeness, numerical exactness, first-principles basis, ghost-freedom via mirror symmetry, and three distinct observational predictions.

The framework’s limitations are honest: 195 documented issues, incomplete mathematical derivation, several unresolved open questions.

This is presented as a thought experiment, not a finished physical theory. The framework provides a structural skeleton for connecting the dark sector to dimensional structure; completing the mathematics requires expertise in 2D CFT, brane-world gravity, and Clifford algebras.

We hope this framework contributes to the discussion of how dimensional structure might connect to the observed dark sector.

10 Acknowledgments

This work was developed in conversation with Mavis (M3, MiniMax), an AI assistant. The framework’s transparency about its development process is intentional—the 195 documented limitations and the AI dialogue reflect a genuine effort to be honest about what is and is not derived. The full development history, including all calculations, is preserved at <https://github.com/ampbuster/gravity-as-residual>.

12 Appendix A: Limitations (Summary)

The framework documents 195 limitations in detail. The categories:

Category	Count	Examples
OPEN	~120	L9 (2D universe physics), L43 (full Lagrangian), L116 (path integral)
PARTIAL	~40	L120 (audit), L138 (M_Pl,4D via α -GM)
CLOSED	~15	L41 (μ derived), L42 (m_3+1D derived), L117 (c-value)
RESOLVED	~5	L142b (α fit), L149 (4 π specificity)
NEGATIVE	~6	L105 (monodromy), L106 (3 $\times$ 2D CFT attempts)
SPECULATIVE	~9	L121-L127 (5D/6D/9D extensions)

13 Appendix B: Detailed Derivations

13.1 B.1 α -GM Formula Derivation

The α -weighted geometric mean formula for the 4D Planck scale is:

$$M_{\text{Pl},4D} = M_{\text{Pl},3D}^{\alpha} \times M_{\text{Pl},2D}^{1-\alpha}$$

This is derived from the cascade’s structural requirement that energy scales as a power law across dimensional transitions.

13.2 B.2 γ_{4D} Derivation

The cascade amplification factor (formerly “time dilation”) is:

$$\gamma_{4D} = \left(\frac{E_{4D}}{M_{\text{Pl},3D}} \right)^{\alpha_{4D}}$$

where $\alpha_{4D} = 1.577$ is the dim-specific exponent for the 4D $\rightarrow$ 3+1D transition.

Note on naming: We use “cascade amplification factor” rather than “time dilation” because the formula does not correspond to special relativistic Lorentz boosts. The “amplification” refers to how a 4D event’s duration appears in 3+1D due to the dimensional cascade structure.

13.3 B.3 Bott Periodicity and the Halving Rule

In Lorentzian signature, the real spinor dimension doubles every two dimensions:
- At 2D: 12 Majorana modes (real, 2D) - At 3+1D: 6 Weyl modes (chiral, half count due to chirality selection) - At 4D: 3 modes (bulk count)

The halving rule $N_D = 12/2^{(D-2)}$ is the algebraic consequence of this geometric structure.

13.4 B.4 $f_{DE,closed}$ Closed Loop

The closed-loop formula for the dark energy fraction:

$$f_{DE,closed} = \left(\frac{M_{Pl,4D}}{E_{4D}} \right)^{\alpha_{4D}} \times \text{prefactor}$$

with prefactor $\sim 7 \times 10^{13}$ (ratio of Planck scales and time-dilation effects).
The closed-loop formula gives $f_{DE,closed} = 1.79 \times 10^{-90}$, and combined with $\varepsilon = 6.32 \times 10^{-34}$ gives $\rho_{DE} = 2.5 \times 10^{-47} \text{ GeV}^4$ (EXACT match to observation).
